A bone registration system is disclosed. The bone registration system may have a device including a scanner arranged to scan a target surface area of bone to obtain scan data and a first communication component. The registration system may have also a first marker positionable on a first portion of bone. The first marker may include a second communication component arranged to transmit a location signal for indicating a position of the first marker in a plurality of dimensions relative to the device. The system may have also a registration unit that compares the scan data with surface data of the bone to generate position data identifying overlapping elements of the scan data relative to the surface data, determines location data from the location signal and determines a location of the first marker on a surface of the bone using the position data and the location data.

ULTRASOUND CT REGISTRATION FOR POSITIONING

PRIORITY CLAIM

The present application claims priority to U.S. Provisional Application Ser. No. 61/499,838 entitled "Ultrasound CT Registration for Positioning" filed on Jun. 22, 2011 and U.S. Provisional Application Ser. No. 61/499,849 entitled "Ultrasound CT Registration for Positioning" filed on Jun. 22, 2011, the entire disclosures of which are incorporated herein by reference.

BACKGROUND

CT (Computed Tomography) is often used to image bones as this permits the construction of high definition three-dimensional images. These high definition images facilitate understanding of fractures, ligament injuries and dislocations and assist in the formulation of treatment strategies. CT scanners, however, are large, bulky devices which are inconvenient for use during treatment procedures. Although ultrasound imaging devices are less bulky and more convenient for use during procedures, the images produced by these devices are less accurate and comprehensive than those produced by CT scanners.

SUMMARY OF THE INVENTION

The present invention relates to a bone registration system. The bone registration system may have a device including a scanner arranged to scan a target surface area of bone to obtain scan data and a first communication component. The registration system may have also a first marker positionable on a first portion of bone. The first marker may include a second communication component arranged to transmit a location signal for indicating a position of the first marker in a plurality of dimensions relative to the device. The system may have also a registration unit that compares the scan data with surface data of the bone to generate position data identifying overlapping elements of the scan data relative to the surface data, determines location data from the location signal and determines a location of the first marker on a surface of the bone using the position data and the location data.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 shows a schematic drawing of a system according to a first exemplary embodiment of the present invention;

FIG. 2 shows a perspective view of the system according to the first exemplary embodiment of the present invention;

FIG. 3 shows a perspective view of a system according to a second exemplary embodiment of the present invention;

FIG. 4 shows a schematic drawing of the system according to the second exemplary embodiment of the present invention;

FIG. 5 shows a perspective view of a system according to a third exemplary embodiment of the present invention; and

FIG. 6 shows a schematic drawing of the system according to the third exemplary embodiment of the present invention.

DETAILED DESCRIPTION

The present invention may be further understood with reference to the following description and the appended drawings, wherein like elements are referred to with the same reference numerals. The present invention relates to a system

2

and method for registering a location of a bone marker on a bone for subsequent treatment of the bone. In particular, the present invention relates to a system and method for determining the relative locations of a handheld device and one or more markers to register the location of a marker on a bone with CT data of the bone. Once a position of the one or more marker on a bone is registered, during a treatment procedure, the movement of the marker may be tracked and the tracking information used to manipulate previously obtained CT image data to accurately track and display the position of one or more portions of bone during a procedure.

As will be described in greater detail hereinafter, the present invention is directed to a system and method for registering a location of the one or more markers positioned on the bone with the CT image data to aid in performing of a medical procedure (e.g., a bone fixation procedure, etc.). The exemplary system and method according to the invention permits the registration of the location of the one or more markers quickly and easily via an intra-operative procedure. Exemplary embodiments of the present invention describe a system and method utilizing a portable device to obtain data which is registered to establish the location of first and second markers on first and second portions of bone on a CT image so that, as the first portion of bone is manipulated during a treatment procedure, movement data may be used to manipulate the CT image to show the movement of the bone. It will be understood by those of skill in the art that although the exemplary embodiments describe first and second markers as positioned on first and second portions of a bone, respectively, the first and second markers may also be positioned on first and second bones that are adjacent to one another or on any other substantially rigid body structures so that a previously obtained CT image of the structures may be manipulated to show motion of the structures during a procedure.

As shown in FIG. 1, a system 100 according to an exemplary embodiment of the present invention comprises a handheld device 102 configured to obtain and transmit ultrasound data 120 (e.g., ultrasound image data) to a tracking system 104. The tracking system 104 registers the ultrasound data 120 with CT data 122 (e.g., a CT image) obtained prior to collection of the ultrasound data 120 to determine a location on the CT data 122 corresponding to the position of the handheld device 102 relative to the CT image, such as a bone, represented by the CT data 122. As would be understood by those skilled in the art, the handheld device 102 may use any known portable ultrasound imaging device including, for example, an ultrasound scanner 110 for obtaining ultrasound images. The handheld device 102 also has an electromagnetic sensor 112 for sensing an electromagnetic field emitted from a signal emitter 114 of a field generator 200. The electromagnetic signal emitter 114 generates an electromagnetic field that is also sensed by a first marker electromagnetic sensor 124 of a first marker 106. An electromagnetic sensor 112 of the handheld device 102 and the first marker sensor 124 communicate with the tracking system 104 by sending thereto device data 126 and marker data 128, respectively, in response to receiving the signal emitted by the signal emitter 114. The device data 126 and marker data 128 provide information on the locations of the device 102 and marker 106, respectively, relative to the field generator 200. The tracking system 104 uses the device and marker data 126, 128 to determine a position of the first marker 106 relative to the handheld device 102.

Using the collected information, the tracking system 104 registers (e.g., correlates) the ultrasound data 120 to the CT data 122 to identify the location of the handheld device 102 relative to, for example, a bone; registers the location of the

handheld device **102** relative to the first marker **106**, and determines a location of the first marker **106** on the image represented by the CT data **122**, which may be shown on a display **118**. In a further embodiment, the electromagnetic signal emitter **114** communicates with a second marker electromagnetic sensor **125** of a second marker **132** to determine the location of the second marker **132** relative to the handheld device **102** to determine a location of the second marker **132** relative to, for example, an image of a bone **108** represented by the CT data **122**. Thus, in an embodiment where the first and second markers **106**, **132** are located on first and second portions of a fragmented bone, the locations of the first and second markers **106**, **132** on the bone may be registered prior to a manipulation of the fragments. Such registration may result in the first and second markers **106**, **132** being used to track movement of the first and second portions of the bone relative to one another by manipulating the CT data **122** to display the motion by moving relative to one another portions of the image represented by the CT data **122** corresponding to the first and second portions of the bone **108**. For example, the CT data **122** may be manipulated to show relative movement between the first and second portions of bone **108** on the display **118** based on the movement of the first and second markers **106**, **132**.

The scanner **110** of the handheld device **102** may take a 2D ultrasound image to obtain ultrasound data **120**. The system **100** then looks through the ultrasound data **120** for portions bearing a similarity of contour to portions of the image represented by the CT data **122** to identify portions of the ultrasound data **120** and the CT data **122** which correspond to the same portion of the bone **108**. The ultrasound data **120** and the CT data **122** may, however, have several points of similarity, requiring the handheld device **102** to take several 2D ultrasound images over discrete periods of time to ensure correct registration between these identified portions of data representing the same portion of the bone **108**. The number of 2D ultrasound images required may depend, for example, on the homogeneity of the contour of the bone and the level of detail in the ultrasound and CT data **120**, **122**, respectively. For example, for long bones with large substantially homogeneous areas, more ultrasound scanning may be required to obtain the registration between the ultrasound and CT data **120**, **122**, respectively. Thus, several candidate locations of the CT data **122** may be identified and additional ultrasound data **120** (e.g., ultrasound images) collected until one of the several candidate locations is confirmed as correctly corresponding to a selected portion of the image represented by the CT data **122**.

FIG. 2 depicts a use of the system **100** for registering the location of first and second markers **106**, **132** on a bone **108** with a CT image of the bone **108**. The electromagnetic sensor **112** provides device data **126**, which includes a position and/or orientation of the handheld device **102** relative to the field generator **200**. In particular, as would be understood by those skilled in the art, a known sensor may be employed as the sensor **112** to provide data on an angular orientation of the handheld device **102** in 6 dimensions, which includes first, second and third dimensions indicating a distance on X, Y and Z axes between the handheld device **102** and the field generator **200** and three dimensions relating to the angular rotation (i.e., Roll-Pitch-Yaw) of the handheld device **102** relative to the field generator **200**. This device data **126** is similarly transmitted to the tracking station **104**.

The electromagnetic signal emitter **114** of the field generator **200** communicates with the first electromagnetic sensor **124** and the tracking station **104** to provide marker data **128**, which includes a position and/or orientation of the first

marker **106** relative to the signal emitter **114**. In particular, the signal emitter **114** emits a signal to the first marker electromagnetic sensor **124**, which senses the position and/or orientation of the first marker **106** in 6 dimensions relative to the field generator **200**. The 6 dimensions include 3 dimensions relating to a distance of the signal emitter **114** from the first marker electromagnetic sensor **124** along X, Y and Z axes and three dimensions relating to the angular rotation (i.e., Roll-Pitch-Yaw) of the signal emitter **114** relative to the first marker electromagnetic sensor **124**. This marker data **128** is then transmitted to the tracking station **104**.

The tracking station **104** may be a computer or other processing arrangement including a processor **116** and a display **118**. The ultrasound data **120**, CT data **122**, device data **126** and marker data **128** may, for example, be saved to a memory **130** of the tracking station **104** and may be used to register the first marker **106** to the CT data **122**. The processor **116** correlates the ultrasound data **120** and the CT data **122** to determine a position of the handheld device **102** relative to image of the bone **108** in the CT data **122**. The processor **116** may then determine a location of the first marker **106** relative to the CT data **122** using the device data **126** and marker data **128**. The location of the first marker **106** may also be displayed on the display **118**. The processor **106** may register in real-time the ultrasound and CT data **120**, **122**, respectively, and determine the location of the first marker **106** on the image represented by the CT data **122** so that a system user may be provided with real-time information regarding completion of the registration process.

After registration of the first marker **106**, a second marker **132** may be positioned on a second portion of the bone **108**. Thus, when registration of the first marker **106** has been completed, the registration procedure discussed above may be repeated for the second marker **132** to register a location thereof. Once the locations of both the first and second markers **106**, **132**, respectively, have been determined relative to the CT data **122**, relative movement between the first and second markers **106**, **132** may be continuously tracked and monitored such that a manipulated CT image showing the relative movement of the first and second portions of the bone **108** may be displayed on the display **118** observable by a surgeon or other user to visualize the reduction of a fracture.

The embodiment depicted by FIGS. 1 and 2 has been described for a situation where the bone **108** in which the first and second markers **106**, **132** are positioned is fractured. The fracture could result in two, three, four, etc., bone fragments in each of which a marker is positioned and its location subsequently registered so that at some point later the relative movement of the markers, and therefore the bone fragment associated with the marker, can be tracked on the CT image whilst the bone fragments are moved. An alternate use of the registration system **100** arises when a bone is in one piece, but it is to be divided by an osteotomy into two or more pieces. In this situation, the registered location of the first marker **106** can be used to identify and register the location of the second and each subsequent marker with the CT data by determining the locations of the second and subsequent markers relative to the first marker with reference to the registered location of the first marker **106**.

Referring again to FIG. 2, a first exemplary technique utilizing the system **100** is shown. An electromagnetic field generator **200** emits an electromagnetic field capable of being sensed in the 6 dimensions described earlier. The electromagnetic field generator **200** comprises at least two coils (not shown). It is noted that although the embodiment of FIG. 2 is depicted with only the first marker **106** including a first sensor **124**, the second marker **132** or any plurality of additional

5

markers may be used without deviating from the scope of the invention. The handheld device **102** is connected to the tracking station **104** by, for example, a wired or wireless connection. The first marker **106** may also be connected to the tracking station **104** via a wired connection, although a wireless connection is also envisioned. The embodiment of FIG. 2 operates in a manner substantially similar to the mode of operation disclosed above. Specifically, a CT scan of the bone **108** is made and the CT data **122** is provided to the tracking system **104**. The first marker **106** is positioned on a first portion of the bone **108** and the ultrasound seamer **110** is used to scan the first portion of the bone **108**. It is noted that the position of the first marker **106** as depicted is exemplary only and that the first marker **106** may be positioned anywhere on the bone **108** without deviating from the scope of the invention. The ultrasound and device data **120**, **126**, respectively, along with marker data **128** for the first marker **106** is transmitted to the tracking station **104** and stored, for example, in a memory **130** and accessed via the processor **116** as required. The processor **116** compares and correlates the ultrasound and CT data **120**, **122** to register the data—i.e., determine overlapping elements in the ultrasound and CT data **120**, **122**. Then, using the device data **126** which indicates a position of the handheld device **102** relative to the field generator **200** and the marker data **128**, which indicates a location of the first marker **106** relative to the field generator **200**, the processor **116** determines a location of the first marker **106** relative to the CT data **122**. Specifically, the processor **116** identifies a position and orientation in 3D space relative to the field generator **200** of the first marker **106** to determine marker data **128**, and the first sensor **112** of the handheld device **102** to determine device data **126**. The processor **116** uses the marker data **128** and device data **126** to determine the relative location of the first marker **106** to the handheld device **102**. The processor **116** uses also the ultrasound data **120** to link the location of the handheld device **102** to the CT data **122** to determine the relative location of the handheld device **102** to the bone **108** in the CT image. Knowing the location of the first marker **106** relative to the handheld device **102** and the location of the handheld device **102** relative to the CT image of the bone **108**, the processor determines the location of the first marker **106** relative to the CT image of the bone **108** and thereby registers the location of the first marker **106** on the CT data **122** and, therefore, the bone **108**. The relative location of the first marker **106** and the CT data **122** may be displayed on the display **118**.

Once the first marker **106** has been registered relative to the CT data **122**, the registration process may be repeated for any number of additional markers (not shown) using the same process as described for registering the first marker **106**. For each additional marker, the ultrasound scanner **110** is used to scan that bone portion in which the bone marker to be registered is located. In this way, movement of a bone fragment during the registration procedure may be compensated. In the situation where the bone **108** is in one piece, a position of the second marker **132** may be detected relative to the first marker **106** to determine a location of the second marker **132** relative to the CT data **122**. The relative location of the second marker **132** may also be displayed on the display **118**. As those skilled in the art will understand, this relative registration process may be used in, for example, osteotomy procedures where the bone **108** is in one piece and the first marker communicates with the second marker to register a location thereof. It is noted, however, that for osteotomy procedures a user may also register the first and second markers individually with the tracking station **104**.

6

In another embodiment of the invention, the registration process may be used for the treatment of scoliosis, with the first and second markers positioned on two different bones, e.g., vertebrae of the spine. In such an embodiment, the first and second markers are individually registered with the tracking station **104**, as also described in greater detail earlier. Thus, once the locations of both the first and second markers **106**, **132** have been determined, the user may move the first and second bones relative to one another and, consequently, move the first and second markers **106**, **132**, relative to one another. The motion between the first and second markers **106**, **132** is used to manipulate the image represented by the CT data **122** so the movement between the first and second bones represented by the motion of the markers **106**, **132** is shown on the display **118** so that a user may monitor movement of bones during treatment. The exemplary system and method according to the invention compensates for inadvertent movement of the bones or fragments since the location of the first and second markers **106**, **132** is taken relative to the field generator **200** and not relative to a position thereof within the body. In yet another scoliosis fixation procedure, 3D ultrasound may be used bypassing the need for a build up a 3D image using slices of a 2D ultrasound image, as those skilled in the art will understand. A fixation procedure for a fractured bone may use a registration process substantially similar to that used for a scoliosis fixation procedure, with the first and second markers positioned on separate portions of the fractured bone.

In an exemplary embodiment, the handheld device **102** the ultrasound scanner may include a Siemens X150 for ultrasound scanning and a VF 10-5 vector transducer. The processor **116** may utilize the live MMGIFusion software developed by Princeton SCR for data acquisition and visualization and the IVUS (Interventional Ultrasound) software prototype developed at CAMP, Technical University of Munich and SCR, Princeton for automatic CT-Ultrasound registration. It will be understood by those of skill in the art, however, that this is an exemplary embodiment only and that other systems may be utilized so long as they facilitate use of the system **100**, as described above.

FIGS. 3-4 depict another exemplary marker registration system and method according to the invention. The system and method of FIGS. 3-4 includes a first marker **106** positionable on the bone **108** including a first marker electromagnetic sensor **124**. In this embodiment the field generator **200** is located on the handheld device **102**. The handheld device **102** and first marker electromagnetic sensor **124** are connected to the tracking station **104** by a wired or wireless connection. The system and method of FIG. 3 operates similarly to that disclosed above with respect to FIGS. 1 and 2. However, since the field generator **200** is located on the handheld device **102**, the position and orientation in 6 dimensions of the first marker **106** relative to the field generator **200** provides the processor **116** with the marker data **128**. For the system of FIGS. 3-4, the processor **116** can register the location of one or more markers without a first sensor associated with the handheld device **102** and device data **126**. Specifically, the first marker electromagnetic sensor **124** provides marker data **128** including a position and/or orientation of the first marker **106** relative to the handheld device **102**, compares the ultrasound data **120** to the CT data **122** and registers a position and/or orientation of the handheld device **102** relative to the CT image of the bone **108**. The marker data **128** and the registered location of the handheld device **102** is then used to register a location of the first marker **106** on the image represented by the CT data **122** by correlating marker data with the registered location of the handheld device **102** relative to the CT image of the bone **108**.

7

FIGS. 5-6 depict a system and method according to another embodiment of the invention. The system and method are substantially the same as described for FIGS. 3-4 with the exception that field generator 200 is replaced with an optical field generator 400 (e.g., light emitting array). Specifically, the handset 102 may communicate with an optical tracking instrument 300 connected to the first marker 106. The optical tracking instrument 300 aids in location and registration of the first marker 106 with the tracking station 104 in accordance with the method described with respect to the embodiment depicted by FIGS. 3-4.

It will be apparent to those skilled in the art that various modifications and variations can be made in the structure and the methodology of the present invention, without departing from the spirit or the scope of the invention. Thus, it is intended that the present invention come within the scope of the appended claims and their equivalents.

What is claimed is:

1. A bone registration system, comprising:
 - a device including a scanner arranged to scan a target surface area of bone to obtain scan data and a first communication component configured to transmit a first location signal for indicating a position of the device;
 - a first marker adapted to be positioned on a first portion of the bone, the first marker including a second communication component configured to transmit a second location signal for indicating a position of the first marker in a plurality of dimensions relative to the device;
 - a processor configured to compare the scan data with stored surface data of the bone to generate position data identifying overlapping elements of the scan data relative to the surface data, to determine location data from the first and second location signals and to determine a location of the first marker relative to a surface of the bone in the surface data using the position data and the location data; and
 - a second marker adapted to be positioned on a second portion of the bone, wherein the first and second markers are configured to communicate with one another to determine relative marker data including a position of the first marker relative to the second marker, wherein the processor is further configured to process the relative marker data to determine a location of the second marker relative to the surface of the bone in the surface data.
2. The system of claim 1, wherein the scan data is ultrasound data and the surface data is CT data.
3. The system of claim 1, further comprising a signal generator configured to generate a reference signal;
 - wherein the first and second communication components are a first sensor and a second sensor, each configured to sense the reference signal and transmit respective location signals to the processor indicating a position of the respective communication component in a plurality of dimensions relative to the signal generator; and
 - wherein the processor determines location data from the location signals to indicate the position of the first marker relative to the device in a plurality of dimensions.
4. The system of claim 3, wherein the reference signal is an electromagnetic signal.
5. The system of claim 1, wherein
 - the first communication component is a signal generator configured to generate a reference signal; and
 - the second communication component is a sensor configured to sense the reference signal and transmit the second location signal to the processor for indicating a position of the first marker relative to the device in a plurality of dimensions.

8

6. The system of claim 5, wherein the signal generator and the sensor are one of electromagnetic and optical.

7. The system of claim 1, wherein the location data indicates a position of the first marker relative to the device in six dimensions.

8. The system of claim 1, wherein respective locations of the first and second markers on the surface of the bone are identifiable using the device.

9. The system of claim 1, further comprising a display showing the location of the first marker relative to the surface of the bone in the surface data.

10. The system of claim 1, wherein the second marker includes a third communication component communicating with the first communication component to determine location data indicating a position of the first communication component relative to the third communication component in a plurality of dimensions.

11. The system of claim 1, wherein the device includes one of an electromagnetic field generator and an optical field generator.

12. A method for bone registration, comprising:

- scanning a target surface area of bone to obtain scan data using a device including a scanner and a first communication component configured to transmit a first location signal for indicating a position of the device;
- positioning a first marker on a first portion of the bone, the first marker including a second communication component configured to transmit a second location signal indicating a position of the first communication component relative to the second communication component in a plurality of dimensions;
- positioning a second marker on a second portion of the bone;
- comparing, using a processor, the scan data with stored surface data of the bone to generate position data identifying overlapping elements of the scan data relative to the surface data, determining location data from the first and second location signals and determining a location of the first marker relative to a surface of the bone in the surface data using the position data and the location data;
- determining relative marker data indicating a position of the first marker relative to the second marker; and
- processing the relative marker data to determine a location of the second marker relative to the surface of the bone in the surface data.

13. The method of claim 12, wherein the scan data is ultrasound data and the surface data is CT data.

14. The method of claim 12, wherein the first communication component is an electromagnetic signal emitter and the second communication component is an electromagnetic sensor.

15. The method of claim 12, wherein the location data indicates a position of the device relative to the first marker in six dimensions.

16. The method of claim 12, wherein the second portion of the bone has a fixed spatial relationship with the first portion of the bone.

17. The method of claim 12, wherein the second portion of the bone has a non-fixed spatial relationship with the first portion of the bone.

18. The method of claim 12, further comprising:

- displaying the location of the first marker relative to the surface of the bone in the surface data on a display.
